

Integrating Renewable Energy in the Iron and Steel Industry: Challenges, Opportunities, and Enabling Approaches

Tsisilile Igogo

Joint Institute for Strategic Energy Analysis

Introduction

- Increase in mineral demand and declining mineral ore grades is expected to increase the energy demands and greenhouse gas (GHG) footprint by mining activities (Norgate et al. 2010; and Lezak et al., 2019).
- This poster focuses on iron and steel industry because it is the widely produced and consumed mineral in the world (see Figure 1).

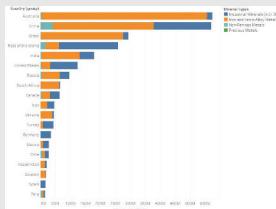

Figure 1. Leading Minerals Producers
Source: Data is from the World Mining Database.

Energy and GHG Intensity

- High volume of global production of iron and steel, and the nature of steel making process make iron and steel production, one the highest consumer of energy and producer GHG emissions within industries.

Table 1. Energy Use and GHG Impacts for 'Cradle-to-Gate' of Select Metals				
Commodity	Feed	Process/route	GER (kWh/t)	
			GHG (Mt CO ₂ eq/t)	
Iron	N/A	Open-cut	43	0.01
Stainless steel	Multiple ores	Electric furnace and Argon/Oxygen decarburization	21,000	6.80
Steel	Iron ore (64% Fe)	Integrated route (BF and BOF)	6,440	2.30

Multiple ores under stainless steel represent: pig iron (94% Fe), chrome ore (27.0% Cr, 17.4% Fe); limestone ore (2.4% Ni, 13.4% Fe) – magnetite ore for steel.

Source: Norgate et al., 2007

- For example, in 2018 crude steel production was about 1,808 million tons (World Steel Association, 2019a).
- If it is assumed that the energy and emission intensity of steel provided by Table 1 is roughly equivalent to what it is in 2018, it implies steel industry used about 11,644 TWh of energy and produced about 3,616 million Mt of CO₂ emission in 2018.

Renewable Use Trend by Miners

- Prior to 2000, the use of renewables in mining operations was nearly non-existent.
- Recent years have seen an uptick in renewable energy adoption by mining companies, with a notable spike in commissioned projects in 2019.

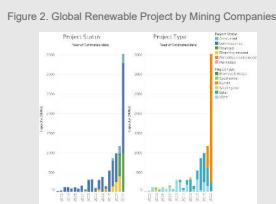

Figure 2. Global Renewable Project by Mining Companies

- Despite this increase in renewable project installations, the aggregate amount of energy generated by these projects is still a fraction of total energy consumed by the mining industry (BNEF, 2019).

Challenges of Using Renewable Energy

- Technical challenges:
 - ✓ Feed stock demand
 - ✓ High temperature process heat demand

Figure 3. Steelmaking
Source: Graph adapted from <https://www.worldcoal.org/>

- Variability of wind and solar
- Mining/plant design and investment structure

Other challenges:

- Conflicting business models
- Lack of technology proof of concept
- Lack of renewable energy awareness and expertise
- Challenge for green supply chain certifications
- Land constraints
- Supply chain

Enabling Approaches

- Research and development
 - ✓ Clean Hydrogen
 - ✓ Increase temperature produced by other renewables
- Alignment of business model and incentives
- Capacity building
- Addressing supply chain certification challenge
- Pooling resources
- Policy and regulations

Renewable Integration Opportunities

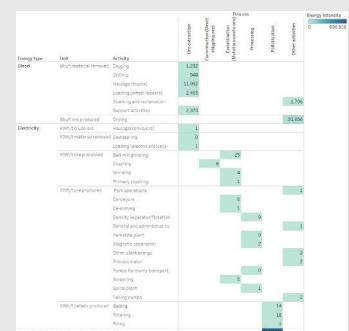

- Table 2 shows of the mining process/operations that could be supported by renewable

Table 2. Mining Processes and Associated Fuel Sources

Mining process	Activities and Equipment	Fuel Source
Exploration and Ancillary Operations	Ventilation: Fan system Drilling: Loader trucks, diamond drills, rotary drills, percussive drills, drill beam jumbos	Electricity, Diesel, Compressed Air
Materials Handling	Waterways: Pump Dredging: Hydraulic dredges, cable stowage, continuous miners, longwall mining machines, drag lines, front-end loaders	Electricity, Diesel
Beneficiation and Processing	Discrete transportation system: Haul trucks, front-end loaders, haulers, hosts Conveyors: Belt Separations: Physical, Flotation, centrifuge, and Chemical Roasting: Furnace Refining: Electrolysis and Electrowinning	Diesel and Electricity

- Disaggregated energy data of iron and steel provide a better understanding of opportunities for renewable use in the industry. Source for steel disaggregate data is limited therefore, this part is going to focus on iron production.

Table 3. Disaggregated Energy Use by the Iron Mining Across the Value Chain

Source: Data obtained from Katta et al., 2020 as compile from several sources such as Natural Resources Canada, US Department of Energy and other studies.

Notes: 1 kWh is equivalent to 3412.14 Btu.

- From table 3, high temperature processes like firing and drying uses fossil fuel. These activities will hard to replace with renewable sources under current technologies (see Table 4).

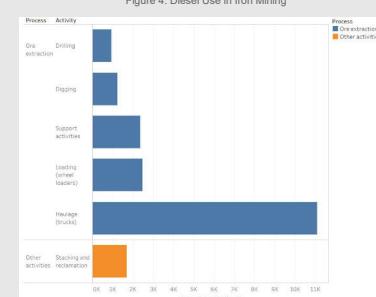

Table 4. Maximum Temperature Supported by Renewable Technology

Category	Technology type	Temperature levels
Renewable source	Biomass, boiler	Low
	Biomass, high temperature	Medium
	Biomass, CHP	High
	Bio-gas, anaerobic digestion	Low
	Solar PV	High
	Wind	High
	Heat pump	Low
	Geothermal direct use	Medium
Energy storage	Solar thermal	N/A
	Hydrogen	N/A
	Pump storage	N/A
	Battery storage	N/A

Source: Data from IRENA, 2015; University of Australia, 2019; and Environmental Protection Agency Note: Low temperature (150 °C), medium temperature (150 °C – 400 °C), and high temperature (>400 °C). *High temperature level production using solar and wind is not yet commercially available. **Hydrogen energy – refers to clean hydrogen generated from renewable electricity and water which is still uneconomical at the moment.

- However, other fossil fuel activities such as digging, drilling, haulage and loading can be electrified by renewable sources.

Figure 4. Diesel Use in Iron Mining

Source: Data obtained from Katta et al., 2020 as compile from several sources such as Natural Resources Canada, US Department of Energy and other studies.
